# 1 Notation

## 1.1 Reference Frames

- $\mathcal{F}_b$ : body-fixed frame attached to the robot.
- $\mathcal{F}_n$ : navigation frame, defined as ENU (East–North–Up).

$\mathbf{R}_{nb} \in SO(3)$  denotes the rotation matrix from body frame to navigation frame.

## 1.2 State and Control

The control-oriented system state is defined as

$$\mathbf{x} = [v_x \ v_y \ v_z \ \omega_z \ a_x \ a_y \ a_z \ \psi]^\top, \quad (1)$$

where

- $(v_x, v_y, v_z)$ : linear velocity expressed in the navigation frame  $\mathcal{F}_n$ ,
- $\omega_z$ : yaw angular rate,
- $(a_x, a_y, a_z)$ : linear acceleration,
- $\psi$ : yaw angle.

The control input is denoted by

$$\mathbf{u} \in \mathbb{R}^m, \quad (2)$$

representing normalized thruster commands.

## 1.3 Temporal Parameters

- Control frequency:  $f_c = 50$  Hz.
- History window length:  $L$ .
- Prediction horizon:  $H$ .

## 1.4 Uncertainty

For any predicted variable  $y$ , the model outputs both mean  $\hat{y}$  and standard deviation  $\hat{\sigma}_y$ .

# 2 Modeling Assumptions

## 2.1 Time-Scale Assumptions

The system is considered at a discrete-time resolution aligned with the control loop. Hydrodynamic effects are assumed to be locally stationary within a short prediction horizon.

## 2.2 Observability Assumptions

- Planar velocity is intermittently observable through DVL measurements.
- Attitude and angular velocity are provided by the onboard IMU fusion algorithm.
- Vertical motion and roll/pitch dynamics are not explicitly modeled.

### 2.3 Applicability Domain

The proposed model targets low-to-moderate speed underwater robots operating in structured environments. Highly aggressive maneuvers and full 6-DOF coupling are outside the current scope.

## 3 Sensor Models

### 3.1 Inertial Measurement Unit (IMU)

The accelerometer measures the specific force:

$$\tilde{\mathbf{a}} = \mathbf{a} - \mathbf{R}_{bn}\mathbf{g} + \mathbf{b}_a + \mathbf{n}_a, \quad (3)$$

where  $\mathbf{g}$  is the gravity vector,  $\mathbf{b}_a$  the accelerometer bias, and  $\mathbf{n}_a$  measurement noise.

The gyroscope measurement is given by

$$\tilde{\boldsymbol{\omega}} = \boldsymbol{\omega} + \mathbf{b}_\omega + \mathbf{n}_\omega. \quad (4)$$

Bias terms are modeled as random walks.

### 3.2 Doppler Velocity Log (DVL)

The DVL provides low-frequency planar velocity observations:

$$\tilde{\mathbf{v}} = \mathbf{v} + \mathbf{n}_v, \quad (5)$$

where  $\mathbf{n}_v$  is non-Gaussian and subject to dropouts. Quality indicators are used to gate valid observations.

## 4 Control-Oriented Dynamics Abstraction

Rather than identifying full hydrodynamic parameters, we model the system response as

$$\mathbf{x}_{k+1} = f_\theta(\mathbf{x}_k, \mathbf{u}_k, \mathbf{h}_k), \quad (6)$$

where  $\mathbf{h}_k$  represents latent hydrodynamic memory states.

The latent dynamics are defined as

$$\mathbf{h}_{k+1} = \boldsymbol{\alpha} \odot \mathbf{h}_k + g_\theta(\mathbf{x}_k, \mathbf{u}_k), \quad (7)$$

with element-wise decay factors  $\boldsymbol{\alpha} \in (0, 1)$  ensuring stability.

This structure captures wake effects, added mass, and other unmodeled fluid interactions.

## 5 Heteroscedastic Uncertainty Modeling

Sensor noise and environmental disturbances are state-dependent and non-stationary. We therefore model predictive uncertainty explicitly.

For a predicted variable  $y$ , the network outputs  $(\hat{y}, \hat{\sigma}_y)$ . Training minimizes the negative log-likelihood:

$$\mathcal{L}_{\text{NLL}} = \frac{\|y - \hat{y}\|^2}{\hat{\sigma}_y^2} + \log \hat{\sigma}_y^2. \quad (8)$$

This formulation allows the model to adaptively down-weight unreliable observations and provides uncertainty estimates usable by downstream controllers.

## 6 Learning Objective

The model is trained for multi-step prediction over a horizon  $H$ .

### 6.1 Prediction Loss

$$\mathcal{L}_{\text{pred}} = \sum_{j=1}^H w_j \|\hat{\mathbf{x}}_{k+j} - \mathbf{x}_{k+j}\|^2. \quad (9)$$

### 6.2 Consistency Constraint

Velocity and acceleration predictions are constrained by

$$\hat{\mathbf{v}}_{k+1} \approx \hat{\mathbf{v}}_k + \hat{\mathbf{a}}_k \Delta t. \quad (10)$$

### 6.3 Total Loss

$$\mathcal{L} = \mathcal{L}_{\text{pred}} + \lambda_c \mathcal{L}_{\text{cons}} + \lambda_u \mathcal{L}_{\text{NLL}}. \quad (11)$$

## 7 Multi-Step Rollout and Stability

Single-step accuracy is insufficient for control. Errors compound during rollout and may destabilize predictive controllers.

The latent-state formulation with bounded decay ensures internal stability, while uncertainty estimates grow with prediction horizon, reflecting reduced confidence.

## 8 Interface to Control Algorithms

At each control step, the model provides

$$(\hat{\mathbf{x}}_{k+1:k+H}, \hat{\Sigma}_{k+1:k+H}), \quad (12)$$

where  $\hat{\Sigma}$  denotes predictive uncertainty.

This interface is compatible with MPC and model-based RL algorithms, which may incorporate uncertainty for risk-sensitive decision making.

## 9 Discussion

The proposed framework prioritizes control usability over full physical fidelity. While not replacing high-fidelity CFD models, it offers a practical compromise between interpretability, stability, and deployment efficiency.

Future work includes extension to full 6-DOF dynamics and online adaptation.

## A Additional Derivations

This appendix will include supplementary derivations and implementation details.
